

How to dissipate heat from batteries

Overview

Designing a battery module or pack requires balancing several competing thermal factors. The most common strategy is to provide just-enough thermal management to achieve the battery pack's fundamental. Maximum charge/discharge rate – How fast can you charge or discharge the battery without damaging the cells from excessive heat?

An EV may have charging requirements as low as 0.5°C, as high as 2.0°C, or even higher. Four primary methods prevent thermal propagation in prismatic and pouch cell packs, and each method has significant consequences for cell cycle lifetime, the ability to fast charge, and driving range. Used alone or combined. In lower-performance battery packs, aluminum has been the primary material, often used for mechanical structure and heat spreading. For higher-performance battery packs, the amount of aluminum needed for safe spreading is the best way to prevent thermal propagation in pouch and prismatic cell battery packs because it prevents propagation while extending cell cycle lifetime and fast charging while cutting size and weight.
